NOTE: This Guide describes the use of ROCCIA MultiLIF as a TLIF, LLIF and as an ALIF instrumentation – it does not replace briefing by a physician experienced in the surgical instrumentation of the spinal column.

We would be happy to assist you in finding a hospital that provides an opportunity to observe surgical procedures.

PREFACE

ROCCIA MULTILIF® – FOR LUMBAR SPINAL FUSION

The ROCCIA MultiLIF was developed for primary stabilisation and restoration of the physiological lordosis in the lumbar spine. The cage is designed for various anterior and posterior approaches.

The special feature of ROCCIA MultiLIF is the possibility of using this cage for two different implantation techniques. Transforaminal access is one approach, but an anterior approach to the spinal column is also possible, either ventromedial or ventrolateral (anterior to the psoas). The numerous threaded holes of ROCCIA MultiLIF allow for accordingly correct placement of the cage.

The ROCCIA instrumentation system, like all Silony Medical products, can be used in a modular manner and is ergonomically designed. Thus, the ROCCIA inserter enables the user to perform various instrumentation steps with just one single instrument. This not only helps to speed up the surgical procedure, but also decreases the need for inventory which then has to be cleaned and stored in the clinic.

With interbody fusion using ROCCIA MultiLIF, we recommend additional posterior spondylodesis with instrumentation using FDA cleared fixation devices such as our VERTICALE posterior spinal fixation system.

Indications

The ROCCIA MultiLIF System is indicated for intervertebral body fusion of the spine in skeletally mature patients. The system is designed for use with autogenous bone graft to facilitate fusion and supplemental internal spinal fixation systems cleared by the FDA for use in the thoracolumbar spine. The devices are to be used in patients who have had at least six months of non-operative treatment.

The ROCCIA MultiLIF implants are intended for use in interbody fusions at one or two contiguous levels in the thoracic spine from T1 to T12 and at the thoracolumbar junction (T12-L1), following discectomy for the treatment of a symptomatic disc degeneration (DDD), including thoracic disc herniation (myelopathy and/or radiculopathy with or without axial pain).

The ROCCIA MultiLIF implants are intended for use at one or two contiguous levels in the lumbar spine, from L1 to S1, for the treatment of degenerative disc disease (DDD) with up to Grade I spondylolisthesis. DDD is defined as back pain of discogenic origin with degeneration of the disc confirmed by history and radiographic studies. The ROCCIA MultiLIF implants can be used as an adjunct to fusion in patients diagnosed with multilevel degenerative scoliosis.

NOTE: ROCCIA MultiLIF must be combined with additional stabilisation. For dorsal lumbar intersegmental fusion procedures, Silony Medical recommends the use of an FDA cleared posterior spinal fixator (e.g. with the VERTICALE system).

Contraindications

Contraindications include, but are not limited to:

- Infection, local to the operative site
- Signs of local inflammation
- Patients with known sensitivity to the materials implanted
- Patients who are unwilling to restrict activities or follow medical advice
- Patients with inadequate bone stock or quality
- Patients with physical or medical conditions that would prohibit beneficial surgical outcome
- Use with components of other systems
- Reusable or multiple uses
- Prior fusion at the level(s) to be treated

NOTE: Please note the advice on indications and contraindications in the package insert of ROCCIA MultiLIF. The package insert also contains other important information that might lead to exclusion of the patient.

POSSIBLE APPROACHES FOR THE ROCCIA MULTILIF® SYSTEM

Thanks to its special shape and wide range of sizes, but especially due to the many threaded holes, ROCCIA MultiLIF can be implanted either as a TLIF or as an ALIF and LLIF.
The difference in its instrumentation lies mainly in the position and approach used.

Instrumentation as TLIF – Position and approach

RI-1410*
ROCCIA Chisel 10 mm,
reinforced

The patient is positioned in the prone position, as is common for the posterior approach. Exposing the abdomen decreases the load on the abdominal vessels. Corresponding bearing frames or padding underneath the pelvis and thorax can be used for this. The main incision is usually performed medially above the spinous processes depending on the spinal segments being treated. The spinal erector muscles are then displaced strictly subperiosteally on both sides and prepared until the anatomical structures of the spinal column are clearly exposed.

The transforaminal approach to the disc space is usually achieved by means of unilateral resection of the facet joint on the approach side (Fig. 1). The 6, 8 or 10 mm ROCCIA Chisels can be used for this, as well as standard instruments such as Luer forceps and swages.

* Representative for other chisels, see ROCCIA Instruments

NOTE: The choice of approach (ventromedial, ventrolateral or strictly lateral) is performed at the surgeon's discretion and as appropriate for the segment being operated on, by identifying the diseased disc space with an image converter.

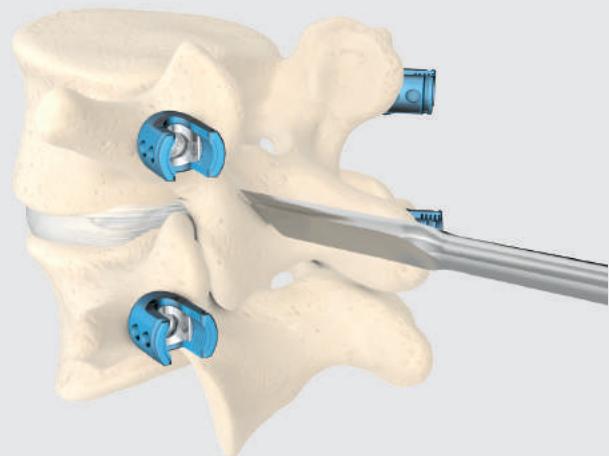

Fig. 1 Resection of a facet joint with the chisel for a TLIF approach

Instrumentation as ALIF and LLIF – Positioning and approach

When implanting ROCCIA MultiLIF for anterior lumbar interbody fusion (ALIF), there are two main positioning options. On the one hand, there is the standard supine position with closed legs and arms abducted at 90° in which the surgeon usually stands to the left of the patient, and, on the other hand, the da Vinci or French position in which the surgeon can stand between the patient's legs. The anteromedial approach may require retraction of the larger vessels to ensure that there is sufficient room to access the disc space to implant the cage. The anterior longitudinal ligament is resected.

In the posterolateral approach (45°), the longitudinal ligament is for the most part preserved. There is no need to retract the larger vessels.

The system also supports the strictly lateral approach (LLIF). In this approach, the patient is positioned either in the lateral or supine decubitus position.

When using the lateral approach, there is no need to retract the larger vessels. Using a direct lateral transpsoatic approach requires careful monitoring of the neurogenic structures present in the muscle.

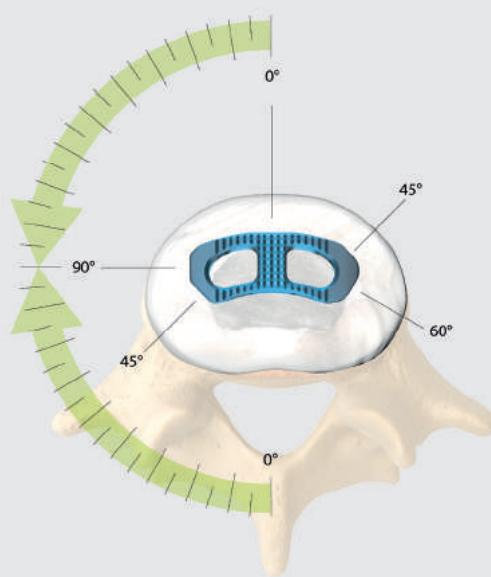

Fig. 2 Note about the degrees used in the thoracolumbar approach

ROCCIA MULTILIF® INSTRUMENTATION

The ROCCIA MultiLIF system was developed for both the transforaminal approach and the anterior approach, and the instrumentation steps outlined in the following thus apply to both the preparation of the implant bed and the implantation of the intervertebral disc space of the aforementioned approaches and surgical techniques.

Discectomy

RI-1020*
ROCCIA Ring Endplate Scraper
Straight

RI-1040**
ROCCIA Curette Straight

RI-1107***
ROCCIA Shaver

GI-3101
T-Handle

To begin with, the disc is incised with a standard scalpel. The disc material is loosened by means of shavers, via the transforaminal approach for Transforaminal Lumbar Intercorporal Fusion (TLIF), or via the anterior approach for Anterior Lumbar Intercorporal Fusion (ALIF), and is then removed using various standard forceps and available endplate scrapers and curettes (Figs. 3 and 4). The fibrous ring is opened up in the process, and the nucleus and the inner fibrous ring are then removed and the surfaces of the end plates are roughened in order to prepare a spacious cage bed.

Various angled endplate scrapers are available to facilitate the removal of the intervertebral disc tissue in the wide lateral disc space.

* Representative for other ring endplate scrapers (angled and curved)

** Representative for other curettes (curved)

*** Representative for other shaver sizes, see ROCCIA Instruments

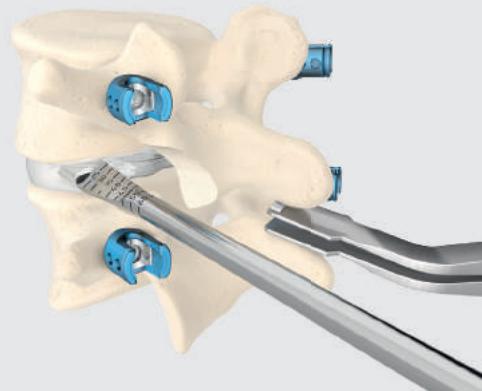

Fig. 3 Loosening of the disc material with a shaver

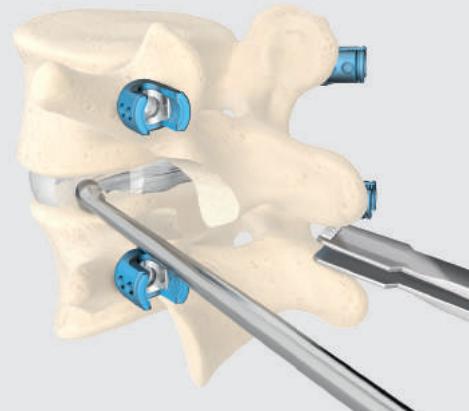

Fig. 4 Discectomy with a curette

NOTE: ROCCIA Shavers are only suitable for mobilising the disc and preparing the cover plates. They must not be used for distraction.

NOTE: When performing implantations using the strictly lateral approach (LLIF), a release of the contralateral part of the fibrous ring is recommended.

NOTE: If possible, the outer fibrous ring should be preserved as support for the cage.

Preparing the disc space

RI-1050

ROCCIA Rasp Curved 45°

RI-1107**

ROCCIA Shaver

GI-3101

T-Handle

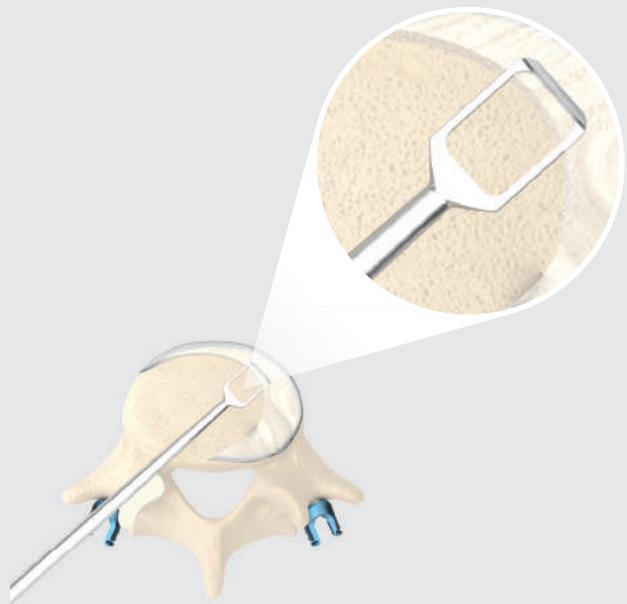

Fig. 5: Box endplate scraper for extensive removal of disc material

For more extensive curettage, the ROCCIA Box Endplate Scraper is also available (Fig. 5). The surface of the remaining cartilaginous layer of the base plate and cover plate can be roughened with bone rasps, curettes and shavers (Fig. 6). The curved endplate scrapers in particular also facilitate the preparation of the opposite side when using the transforaminal approach.

* Representative for other ring endplate scrapers (angled and curved)

** Representative for other shaver sizes, see ROCCIA Instruments

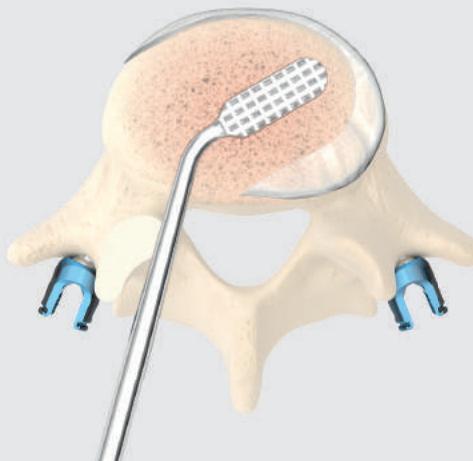

Fig. 6: Rasp for roughening the cover plates

NOTE: Careful preparation of the disc space, especially extensive roughening of the end plates, provides the basis for better vascularisation and successful bone fusion. Damage of the bony base and cover plate can lead to sinking of the implant into the vertebral body.

Distracting the disc space

RI-1207*
ROCCIA Paddle Sizer 7 mm

GI-3101
T-Handle

Blunt ROCCIA Paddle Sizers are available for distraction. They start with a height of 7 mm, and the height increases in steps of 1 mm up to a height of 13 mm; after that, the height increases in steps of 2 mm up to a maximum height of 21 mm. At the distal end of the paddle sizers, there are depth markings between 20 mm and 60 mm in 5-mm steps (Fig. 7).

The paddle shavers are connected to the T-handle by means of a quick-release system. For better orientation, the handle ends are aligned in the same way as the end of the paddle shavers. Two T-handles are available to enable rapid instrumentation.

For distraction, the blunt 7 mm paddle sizers is first inserted into the disc space and erected by 90° rotation (Fig. 8). The next paddle sizers are then inserted in steps of 1 mm with the same movement until the desired height is achieved. The appropriate distraction height is achieved when the paddle shaver is under tension and provides a feeling of stability. Standard lamina spreader forceps can additionally be used for distraction.

* Representative for other distractor sizes, see ROCCIA Instruments

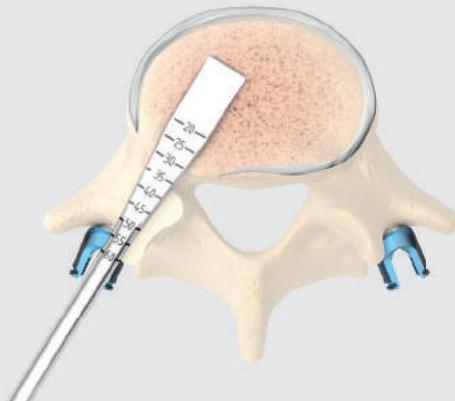

Fig. 7 Depth marking on the distractor

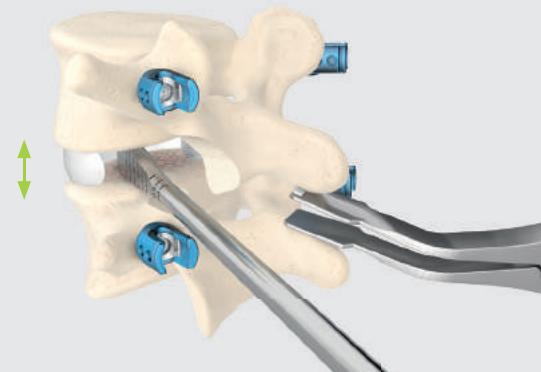

Fig. 8 Spreading the disc space with the distractor

NOTE: Overdistraction should be avoided. This increases the risk of damaging the base plates and cover plates and subsequent sinking of the implant, and jeopardises the restoration of physiological lordosis.

Selecting the trial implant

RI-1324

RI-1325
ROCCIA Inserter M5,
dismountable

RI-1207*
ROCCIA Paddle Sizer 7 mm

GI-3101
T-Handle

To determine the size of the disc space, the blunt distractors are available with depth markings between 20 and 60 mm in 5 mm steps. The heights 7 mm - 13 mm in 1 mm steps and 15 mm and 17 mm correspond to the eventual implant. Trial implants can be selected on the basis of these measurements and under image converter control (Fig. 9).

An appropriate trial implant with 5° or 15° lordosis is available for each definitive cage size. The trial implants are marked analogously to the implants to be implanted later on. The colour marking facilitates identification of the matching inserter, which has coloured rings on the instrument stem.

The trial implants correspond to the subsequent ROCCIA MultiLIF size. The height of the cage interlock on the definitive implant was taken into account when selecting the trial implants.

* Representative for other distractor sizes
see ROCCIA instruments

RI-T113405*
ROCCIA MultiLIF Trial
11 x 34 mm 5°

ROCCIA inserters are required to insert the trial implants. The ROCCIA inserters fit onto both the trial implants and the definitive implants. The selected trial implant is screwed onto the respective ROCCIA Inserter and then, applying mild pressure, carefully inserted into the intervertebral space via the transforaminal window or accordingly when using the anterior approach (Fig. 10). At the surgeon's discretion a mallet can also be used to insert the trial. After that, the position and size of the trial implant is verified in the image converter.

To ensure that the height of the intervertebral disc is preserved after loosening the distraction, the implant must fit between the end plates after full distraction of the segment.

Using the largest possible implant for each individual patient maximises the stability of the segment.

If the trial implant does not sufficiently fill in the intervertebral disc space, the next larger implant must be used. If the trial implant cannot be inserted because the intervertebral disc space is too small, either the next smaller size has to be used or the segment has to be distracted further using the aforementioned instruments. Once the correct size has been determined, the distraction can be temporarily loosened.

* Representative for other trial implant sizes see ROCCIA Trial implants

Fig. 10 Introducing the trial implant

NOTE: Correctly selecting the cage size has a decisive impact on the success of the instrumentation and fusion.

Multitude of cage sizes

To optimise the treatment of the patient in terms of anatomy and pathology, a wide range of ROCCIA MultiLIF sizes is available (Fig. 11). The portfolio comprises nine anterior heights (from 7 to 13 mm, in 1-mm increments, and the heights 15mm and 17mm) and five widths (34, 40, 46, 52 and 58 mm). In addition to the regular lordotic angles of 0°, 5° and 10°, hyperlordotic cages with an angle of 15° are also available.

The inserter with the respective colour code corresponds to the respective cage.

The wide cage sizes (46, 52, 58 mm) are recommended for the lateral (90°) approach (LLIF). Following discectomy, the cage is positioned in the target segment. Care should be taken to ensure that it rests as much as possible laterally and contralaterally on the end plates.

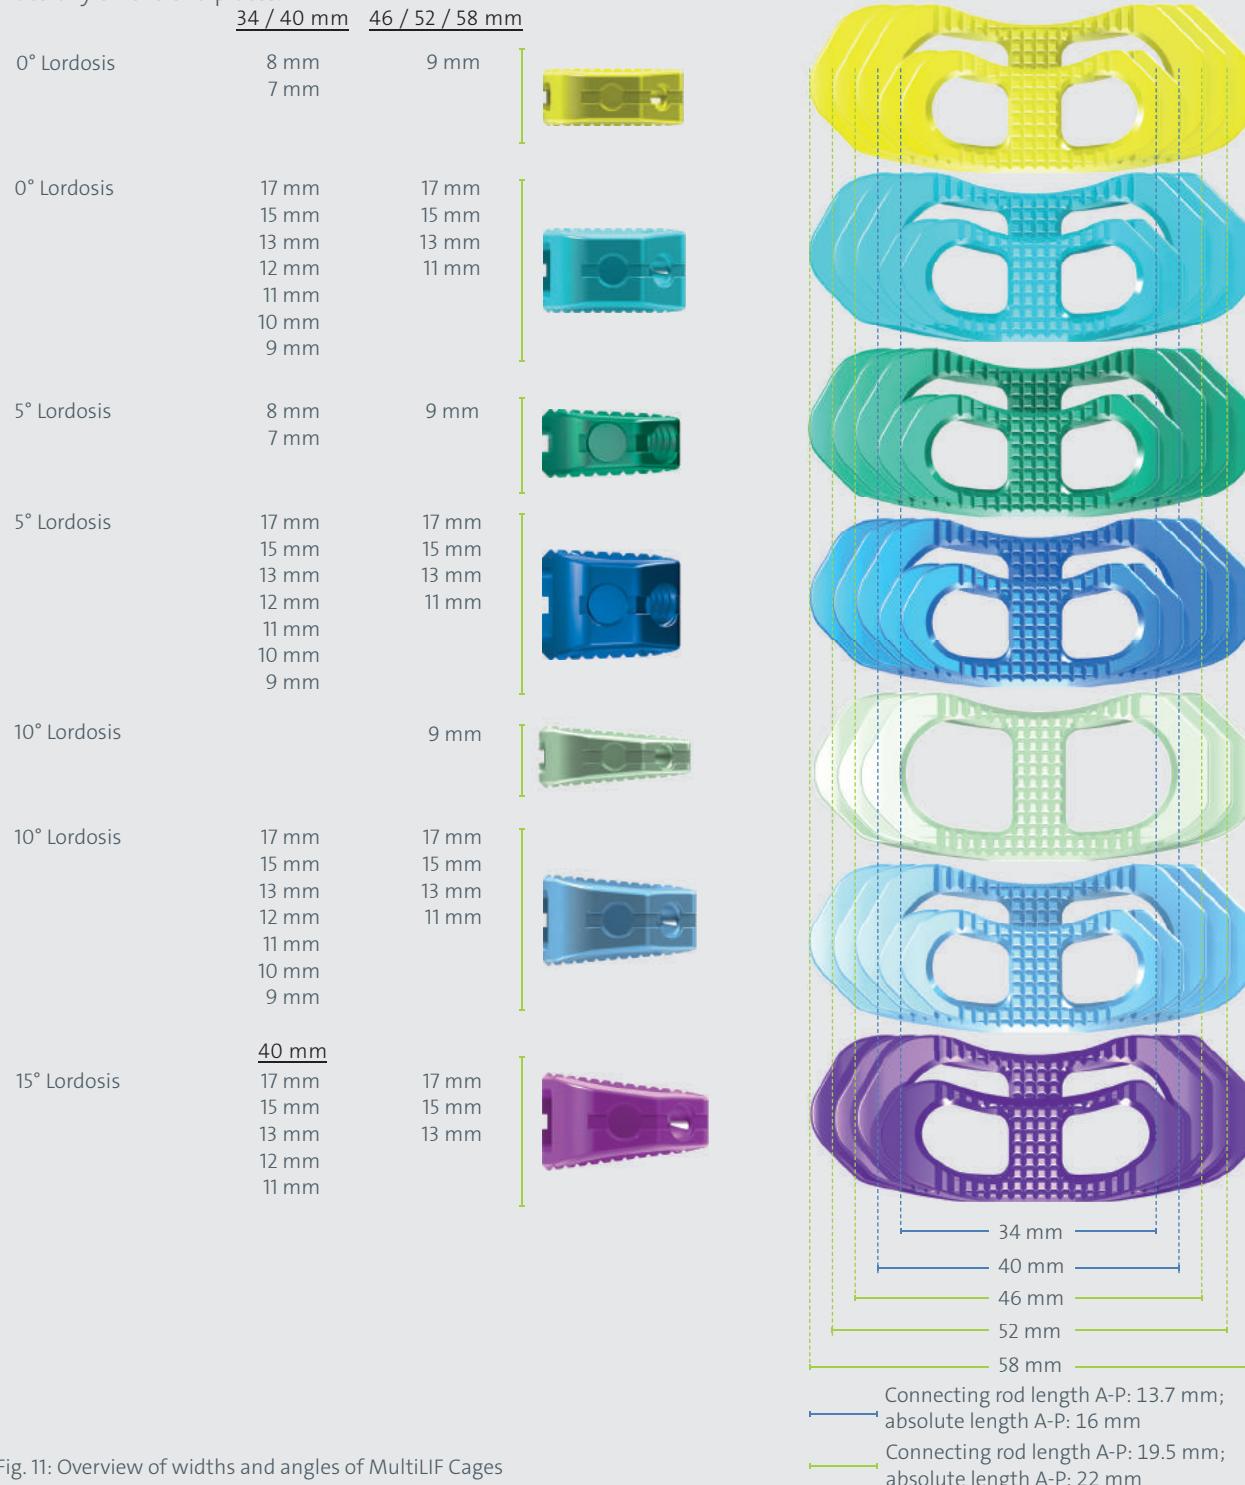

Fig. 11: Overview of widths and angles of MultiLIF Cages

Filling the cage

RI-1324

RI-2050*
ROCCIA Implant Loading Block

RI-2051
ROCCIA Bone Graft Pusher

RI-1355
ROCCIA Slotted Mallet, solid

Remaining areas of the intervertebral disc space can be filled with autologous bone (e.g. from the iliac crest) either before or after implantation of the cage in order to achieve the largest possible fusion surface area. Filling of the disc space, but also filling of the implant, is an important prerequisite for secure fusion. A loading block and a pusher are provided for this (Fig. 12).

To ensure comfortable insertion when using the TLIF approach, the existing threaded holes on the ROCCIA MultiLIF allow for various dorsolateral angles (60° , 45°). A ventromedial drill-hole in the implant is available for the ALIF approach. In addition, the cage has a drill-hole at 45° and a strictly lateral drill-hole at 90° for the ventrolateral approach.

* Representative for other loading blocks, see ROCCIA instruments

Inserting the cage

RI-1324
ROCCIA Inserter M4,
dismountable

RI-1325
ROCCIA Inserter M5,
dismountable

RI-1355
ROCCIA Slotted Mallet, solid

The ROCCIA inserter, which is used in the same way as previously for the trial implants, is screwed accordingly into one of the threaded holes of the cage, enabling the cage to be definitively inserted without requiring any further instrument change (Fig. 13 a-d). The autologous bone material must be inserted well compressed into the cage.

The trial implant is removed just shortly before final insertion of the implant in order to prevent subsequent sinking. Depending on the previously selected approach (Fig. 13 a-d), the filled implant is carefully inserted into the disc space and the correct alignment of the implant is verified. Slight pressure or careful hammering with the ROCCIA Slotted Mallet on the implant holder may be required.

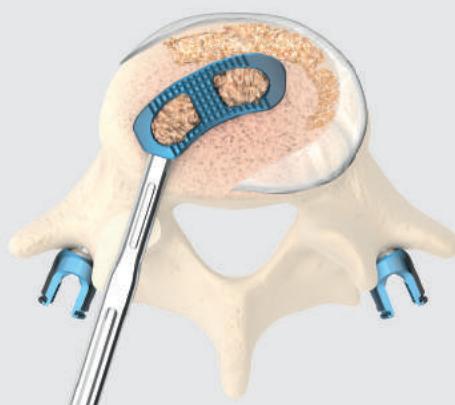

Fig. 13a Inserting the filled cage into the disc space via the TLIF approach (45°)

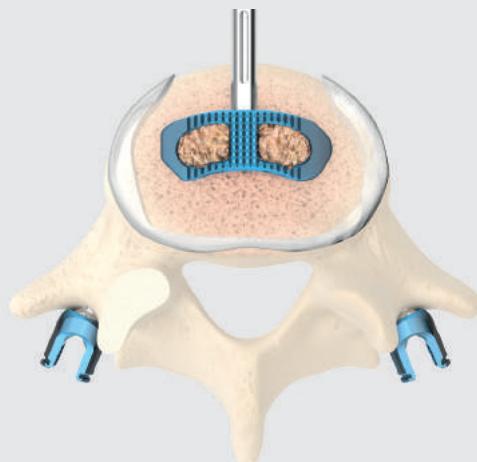

Fig. 13b Inserting the filled cage via the ALIF 0° approach

Fig. 13c Inserting the filled cage via the ALIF 45° approach

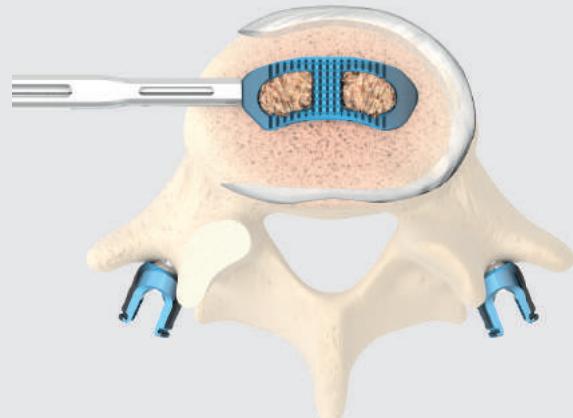

Fig. 13d Inserting the filled cage via the LLIF 90° approach

Correct position of the ROCCIA® MultiLIF

If possible, when using the TLIF approach, the inserter is left in the cage until an AP image and a lateral image with the image converter confirm the correct position of the cage.

For biomechanical reasons, the optimal position of the implanted ROCCIA MultiLIF cage should be in the anterior to middle third of the disc space, centered as far as possible in the frontal projection (guided by the spinous processes or pedicles, Fig. 14a and 14b).

The more anterior the cage is positioned, the better lordosis can be achieved in the respective section of the spine.

Once it has been successfully implanted, the remaining disc space should be filled up to ensure secure fusion.

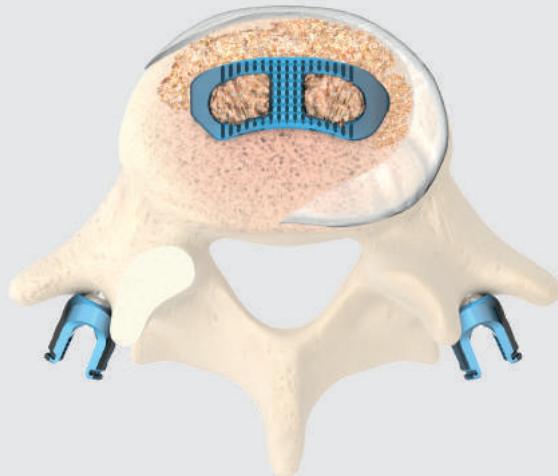

Fig. 14a Optimal position of the filled MultiLIF Cage

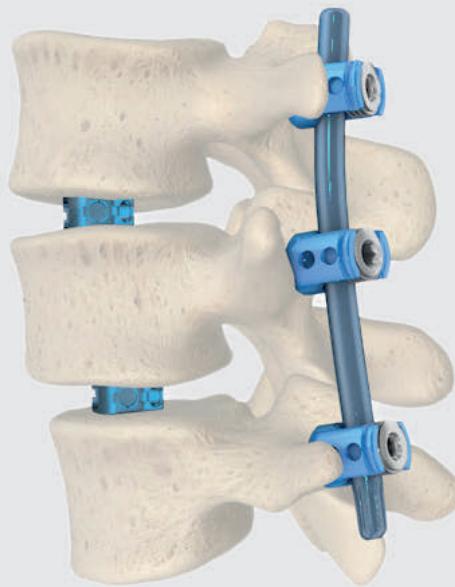

Fig. 14b Optimal position of the filled MultiLIF Cage including posterior fixation

NOTE: Posterior tension band wiring with the VERTICALE Posterior Spinal Fixator is recommended (or posterior or anterior securing of the implant when using the anterior approach). Tension band wiring supports the biomechanical stability of the motion segment of the spine and the stability of the MultiLIF Cage.

The final steps of posterior fixation (e.g. insertion of the rod, compression and final tightening of the set screws) are completed after implantation of the cage.

NOTE: When implanting a MultiLIF Cage with 15° lordosis, it is imperative to provide the segment with additional stabilisation using a fixation system or anterior plating.

CORRECTING THE POSITION OF THE ROCCIA MULTILIF® CAGE

A straight implant driver and a hooked implant driver are available for definitive positioning of the ROCCIA MultiLIF Cage. The use of these instruments is outlined below.

Hooked implant driver

RI-1343
ROCCIA Hooked Implant Driver,
reinforced

RI-1355
ROCCIA Slotted Mallet, solid

The reinforced ROCCIA Hooked Implant Driver is inserted into the drill-hole of the cage (Fig. 15). The shape of this hooked implant driver provides good stability for the desired correction, which can be carried out with the aid of the slotted mallet.

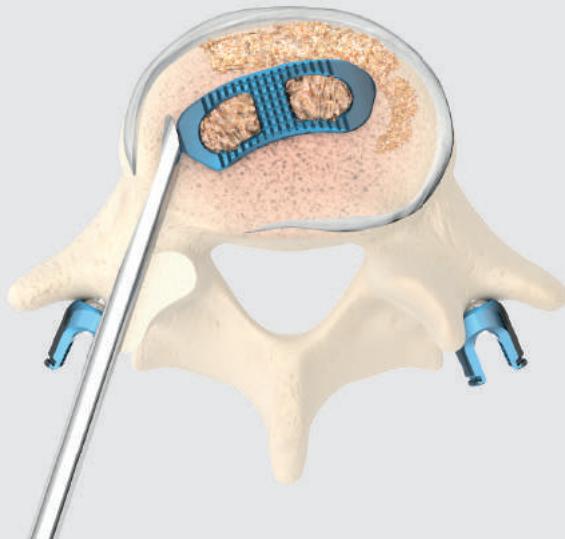

Fig. 15: Hooked implant driver for correcting the position of the cage

Implant Driver Straight

RI-1340
ROCCIA Implant Driver Straight

RI-1355
ROCCIA Slotted Mallet, solid

The ROCCIA Implant Driver is positioned straight onto the lateral posterior front of the cage (Fig. 16). The cage can then be carefully moved into the desired position with the slotted mallet.

Fig. 16: Straight implant driver to finalise the position of the cage
